

STRUCTURE COMPRISING A BINDER LAYER NON-DELAMINABLE
WITH RESPECT TO A METALLIZED SUBSTRATE AND PEELABLE
WITH RESPECT TO A POLYPROPYLENE SUBSTRATE

D. C. 11.01

5 The present invention relates to a structure
comprising a polypropylene-based binder layer, that can
be extrusion-coated at high speed onto a metal foil or
a sheet of metallized substrate, having a non-
delaminable character with respect to a completely or
10 partially metallic layer and having a peelable
character with respect to a polypropylene layer.

 The present invention also relates to its use
in the manufacture of metal/plastic packages, such as
drink cartons, food cans, aerosol cans, paint cans and
15 containers and covers for *inter alia* food.

 Patent US 5 235 149 describes containers sealed
by covers. The binder layer of the cover consists of
various polymers grafted by acrylic acid or maleic
anhydride; the polymers may be chosen from
20 polyethylene, polypropylene, ethylene/vinyl acetate
copolymers and ethylene/methyl acrylate copolymers.

 Patent DE 19 535 915 A describes a grafted
polypropylene block copolymer for bonding polypropylene
films to metal foils.

25 Patent EP 689 505 describes structures which
are similar to those described in the previous patent
but which are used for making food packages.

 Patent EP 658 139 describes structures similar
to those described in the previous patent but the
30 binder is a grafted polypropylene random copolymer
comprising from 1 to 10% of a comonomer, the M_w/M_n ratio
is between 2 and 10 and the MFI (Melt Flow Index) is
between 1 and 20 g/10 min. (at 230°C/2.16 kg).

 A package in the form of a container with a
35 cover as opening means must be easy to open and
therefore easily peelable and must be opened cleanly
and neatly. However, the peeling, which depends on the
nature of the binder used to bind the cover to the
container, does not always take place correctly and

According to one embodiment of the structure, the heat treatment is carried out by infrared radiation, by passing it through a hot-air or

induction-heating tunnel, the metal layer being heated to a temperature above the melting point of the binder.

According to one embodiment of the structure, the said structure comprises a polypropylene layer
5 having a melting point above the melting point of the binder, the binder layer being sandwiched between the metal or metallized-substrate layer and the polypropylene layer.

According to one embodiment of the structure,
10 the said structure is peelable with a peel force for peeling the binder layer off the polypropylene layer of between 8 and 15 N/15 mm.

According to one embodiment of the structure the extrudable binder comprises by weight:

15 - 5 to 30% of a copolymer (A) based on ethylene and one or more comonomers chosen from the group of carboxylic acid esters, vinyl esters and dienes;

- 40 to 93% of a stretchable polypropylene (B), stretchability being defined as the ability of a rod
20 extruded at a temperature of between 190°C and 240°C and pulled at a pull rate of between 50 and 250 m/min. not to break;

- 2 to 30% of a polypropylene (C) functionalized by an unsaturated carboxylic acid anhydride;
25 the MFI of the composition being between 10 and 50 g/10 min. (at 230°C/2.16 kg).

According to one embodiment of the structure, the copolymer (A) of the binder is an ethylene/alkyl (meth)acrylate copolymer containing from 5 to 40% and
30 preferably from 10 to 40% by weight of alkyl (meth)acrylate, the MFI being between 0.5 and 200 g/10 min. (at 190°C/2.16 kg).

According to another embodiment of the structure, the copolymer (A) of the binder is an
35 ethylene/alkyl (meth)acrylate/maleic anhydride copolymer containing from 0.2 to 10% by weight of maleic anhydride and from 2 to 40% and preferably from 5 to 40% by weight of alkyl (meth)acrylate, the MFI being between 0.5 and 200 g/10 min. (at 190°C/2.16 kg).

According to another em

Brief Description of Drawings

Figure 1a shows, in cross section, part of a closed food package comprising a cover having a two-layer structure according to the invention.

Figure 1b shows, in cross section, part of a closed food package comprising a cover having a three-layer structure according to an embodiment of the invention.

Figure 2a shows, in cross section, the package in Figure 1a when partially opened.

Figure 2b shows, in cross section, the cover of Figure 1b when partially open.

We will now describe a food package comprising a cover and a container, the said cover having a structure according to the invention. It is clear that the invention is applicable to any type of package and is not limited to only food packages.

A package of solid goods is generally composed of a container (3) and a cover (4). The container (3) is sealed by the cover (4) when the package is in the closed position.

The container (3) may be made of polypropylene or of another, possibly multilayer, material. When the container (3) is a multilayer, it then comprises an external layer (1), for example of aluminium, covered with an internal polypropylene layer (2), the internal layer being in direct contact with the food, unlike the external layer.

The cover (4) consists of layers bonded together which are, in order: a metal or metallized-substrate layer (5), a binder layer (6) as shown in Figure 1a and optionally a polypropylene layer (7) as shown in Figure 1b. The cover is heat-welded on the same side as the binder (6), or optionally on the same side as the polypropylene (7) when the latter is present, to the polypropylene layer (2) of the container (3), in general around its perimeter. Part of the cover (4) is left to extend beyond the opening surface of the container (3) in order to be able to get hold of the latter easily and to open the package. By pulling on the cover (4), a cohesive failure within the binder layer (6) of the cover (4) is induced at the weld. The binder layer (6), and optionally the polypropylene layer (7), tears, interrupting the cohesive failure. The cover and the container shown in Figures 2a and 2b are therefore obtained.

A little binder (6) and possibly the polypropylene layer (7) are left on the container (3) of the open package at the weld. A little binder (6)

and the aluminium layer (5) are left on the cover (4) at the weld (see Figures 2a and 2b). At the points where the cover (4) was not welded to the container (3), the original structure of the cover is found, namely the aluminium layer (5) bonded to the binder layer (6) which is itself bonded to a polypropylene layer (7).

The binder (6) allows the cover (4) to adhere to the container (3) and also allows the cover to be peeled off without it being necessary to use a large force. A child must in fact be able to pull off the cover and open the package.

The cover (4) is manufactured by coextruding the binder layer (6) and the optional polypropylene layer (7), followed immediately by coating them onto the aluminium foil (5) or any other metallized substrate. Once the container has been filled, the cover (4) is fastened by hot welding around the edges of the container (3).

Depending on the nature of the food and the nature of the possible impurities contained in the binder (6), it is possible to use covers that do not include the polypropylene layer (7).

The extrudable binder comprises by weight, the total being 100%:

- 5 to 30% of a copolymer (A) based on ethylene and one or more comonomers chosen from the group of carboxylic acid esters, vinyl esters and dienes;

- 40 to 93% of a stretchable polypropylene (B), stretchability being defined as the ability of a rod extruded at a temperature of between 190°C and 240°C and pulled at a pull rate of between 50 and 250 m/min. not to break;

- 2 to 30% of a polypropylene (C) functionalized by an unsaturated carboxylic acid anhydride;

the MFI of the composition being between 10 and 50 g/10 min. (at 230°C/2.16 kg).

With regard to the ethylene-based copolymer (A), as comonomers mention may be made of:

5

10

- dienes such as, for example, 1,4-hexadiene;

- the polyethylene may contain several of the

15

20

- linear low-density polyethylene (LLDPE);

- very low-density polyethylene (VLDPE);

25

30

35

- EPR (ethylene-propylene rubber) elastomers;

- EPDM (ethylene-propylene-diene) elastomers;

- blends of polyethylene with an EPR or an EPDM.

5

10

25

3.5

It is possible to use a blend of several copolymers (A), whether this is a blend of non-functionalized copolymers, a blend of a functionalized copolymer with a non-functionalized copolymer or a
5 blend of two functionalized copolymers.

By way of example, it is also possible to use a blend of an ethylene/alkyl (meth)acrylate copolymer and an ethylene/alkyl (meth)acrylate/maleic anhydride copolymer.

10 Non-grafted acrylate copolymers (A) are commercially available. They are produced by radical polymerization at a pressure that can be between 200 and 2500 bar and are sold in granule form.

With regard to the polypropylene (B), this is a
15 propylene homopolymer or copolymer. By way of comonomers, mention may be made of:

- alpha-olefins, advantageously those having from 3 to 30 carbon atoms. As examples of alpha-olefins, mention may be made of: propylene, 1-butene, 1-pentene,
20 3-methyl-1-butene, 1-hexene, 4-methyl-1-pentene, 3-methyl-1-pentene, 1-octene, 1-decene, 1-dodecene, 1-tetradecene, 1-hexadecene, 1-octadecene, 1-eicocene, 1-dococene, 1-tetracocene, 1-hexacocene, 1-octacocene and 1-triacontene. These alpha-olefins may be used by
25 themselves or as a blend of two or more of them;

- dienes;

(B) may also be a polypropylene block copolymer.

By way of example of a polymer (B), mention may be made of:

30 - polypropylene;
- blends of polypropylene with EPDM or EPR which may also contain from 1 to 20% polyethylene.

Advantageously, the polymer (B), which may be a blend of several polymers, contains at least 50 mol%
35 and preferably 75 mol% propylene.

The polypropylene (B) is chosen from those of so-called "extrusion coating" grade having an MFI of between 20 and 40 g/10 min. (at 230°C/2.16 kg).

With regard to the polypropylene (C) functionalized by an unsaturated carboxylic acid anhydride, this is a propylene homopolymer or copolymer functionalized by grafting. It would not be outside the scope of the invention to use unsaturated carboxylic acids and the derivatives of these acids and anhydrides. By way of example, mention may be made of acrylic acid, methacrylic acid, maleic acid, fumaric acid, itaconic acid, crotonic acid, itaconic anhydride, nadic anhydride, maleic anhydride and substituted maleic anhydrides such as, for example, dimethylmaleic anhydride. As examples of derivatives, mention may be made of salts, amides, imides and esters, such as sodium monomaleate and dimaleate, acrylamide, maleimide and dimethyl fumarate. The (meth)acrylic acid may be completely or partially neutralized by metals such as Zn, Ca and Li.

Advantageously, a polypropylene having an MFI (Melt Flow Index) of 0.1 to 10 g/10 min. (at 230°C/21.6 kg) is grafted by maleic anhydride in the presence of initiators such as peroxides. The amount of maleic anhydride actually grafted may be between 0.01 and 10% by weight of the grafted polypropylene. The grafted polypropylene may be diluted with polypropylene, EPR or EPDM rubbers, or propylene/alpha-olefin copolymers. It is also possible, according to another alternative embodiment, to co-graft a blend of polypropylene and EPR or EPDM, that is to say to add an unsaturated carboxylic acid, an anhydride or derivatives thereof to a blend of polypropylene and EPR or EPDM in the presence of an initiator.

As other examples of (C), mention may be made of blends comprising by weight:

- 0 to 50% and preferable 10 to 40% of at least one polyethylene or at least one ethylene copolymer;
- 50 to 100% and preferably 60 to 90% of at least one polymer chosen from polypropylenes and propylene copolymers

these blends being grafted by a functional monomer chosen from carboxylic acids and derivatives thereof, acid chlorides, isocyanates, oxazolines, epoxydes, amines and hydroxydes, and preferably anhydrides of unsaturated dicarboxylic acids, these grafted blends possibly being diluted in at least one polyolefin essentially comprising propylene units or in at least one polymer having an elastomeric character or in blends thereof.

Advantageously, (C) contains 0.8 to 4.5% by weight maleic anhydride.

The proportion of (C) in the binder depends on the amount of maleic anhydride; according to a preferred embodiment, if (C) contains from 1.5 to 6% by weight of anhydride, all that is required is to put 1.5 to 6% thereof in the binder. According to another preferred embodiment, if (C) contains from 0.8 to 1.5% by weight of anhydride, all that is required is to put 10 to 25% thereof in the binder.

According to another preferred embodiment, if (C) contains from 1.5 to 3% by weight of anhydride, all that is required is to put 3 to 5% thereof in the binder.

The binder is manufactured by melt blending the various constituents (A), (B) and (C) in the usual machines for blending thermoplastics, such as mixers and extruders.

The binder may also contain additives such as antioxidants, antiblocking agents and processing aids such as fluoropolymers, these additives being used in the usual amounts known to those skilled in the art.

The binder may contain the additives normally used when processing polyolefins, having contents of between 10 ppm and 5% by weight, such as antioxidants based on substituted phenolic molecules, UV stabilizers, processing aids such as fatty amides, stearic acid and its salts, fluoropolymers known as agents allowing extrusion defects to be avoided, amine-based antifogging agents, antiblocking agents such as

silica or talc, master batches with one or more colorants and nucleating agents among others.

The present invention relates to a structure comprising, in succession, a metal foil or a sheet of a metallized substrate, a layer of the above binder and, optionally, a polypropylene layer. This structure is useful for making covers for packages. The invention also relates to these covers and to the packages sealed by these covers.

With regard to the structure comprising, in succession, a metal foil or a sheet of a metallized substrate, a layer of the above binder and optionally a polypropylene layer, by way of example of metal mention may be made of aluminium, steel, tinplate and metallized substrates such as polyester (PET). The thicknesses are, for example in μm , 20/10/10, respectively. The polypropylene of the optional layer placed against the binder may be chosen from the polypropylenes mentioned in the case of (B).

The present invention also relates to a cover comprising the structure according to the invention. The covers usually comprise an aluminium foil on which is coated, by extrusion coating, a binder layer which is itself possibly coated on a polypropylene layer, forming in this case an (Al/binder/PP) sandwich structure. A manipulatable multilayer structure is thus obtained. Next, the binder is activated by a heat treatment consisting in raising the assembly to a temperature of between 160 and 300°C for a few seconds. This heat treatment for activating the binder, by increasing its adhesive properties has the effect of making the metal layer non-delaminable from the binder layer. The duration and temperature of the heat treatment are determined according to the melting point of the binder, to the nature of the metal layer and to the desired result. The temperature of the heat treatment must in any case be greater than or equal to the melting point of the binder and less than the melting point of the polypropylene layer when the

latter is present in the structure. The heat treatment may be carried out in line after the extrusion coating or subsequently, the adhesion between the metal layer and the binder before the heat treatment being
5 sufficient to allow reels to be formed and to allow unreeling from the reels.

The covers are then hot welded to polypropylene containers or containers made either of polypropylene or of a material covered with polypropylene, it being
10 possible for the said material to be aluminium, polyester or polystyrene.

Peel tests were carried out on covers (4) and containers comprising a cover (4) and packages comprising a cover (4) welded onto a polypropylene
15 container (3).

The covers (4) used in these tests had a two-layer structure (see Figures 1a and 2a) comprising an aluminium layer (5) 30 μm in thickness and a binder layer (6) 30 μm in thickness. This multilayer structure
20 was obtained by extrusion-coating the binder layer onto the aluminium layer. The structure then was made to pass through a hot-air tunnel set to a temperature of greater than 220°C for a few seconds so as to activate the binder and obtain high adhesion. This is the so-called heat treatment. Next, the cover (4) was welded
25 to the container (3). During this welding operation, the binder layer (6) was welded directly to the polypropylene container. A package as shown in Figure 1a was then obtained. The binder (6) used for
30 these tests comprised 17% by weight of PP grafted with 0.8% by weight of maleic anhydride (MAH), 17% of an ethylene/ethyl acrylate/MAH terpolymer in proportions by weight of 68/30/2 respectively, and 66% of coating homopolymer PP.

35 Peel tests measuring the peel strength between the aluminium layer (5) and the binder layer (6) were carried out on three covers having the structure and composition as described above, before heat treatment and after heat treatment (passing them for a few

0004196-033004

seconds through a hot-air tunnel set to a temperature of greater than 220°C). The peel force was measured at a rate of 100 mm/min according to the NFT 54120 and NFT 54122 standards. On three covers, these peel forces
5 before heat treatment could not be measured as they were too low, whereas those after heat treatment characterize a non-delaminable structure.

It is clearly apparent that the heat treatment makes it possible to obtain a non-delaminable metal
10 layer (5)/binder layer (6) structure.

The peel force needed to peel the cover off the container or the opening force required to open it was then measured at a rate of 200 mm/min. according to the NFT 54120 Standard and the NFT 54122 Standard. Three
15 packages (cover + container) were prepared and the results obtained are given in TABLE 1 below:

TABLE 1

Package	Peel force (N/15 mm)
Package No. 1	10 - 13
Package No. 2	9 - 11.5
Package No. 3	9 - 11

20

These packages were opened cleanly and neatly, without the cover tearing other than at the weld zone, as shown in Figure 2a.

The peel force values obtained demonstrate the
25 easy peelability of the covers and therefore the ease with which packages having such covers can be opened.

The same peel tests were carried out on:

- three-layer covers with a PP layer (7) 30 µm in thickness, a binder layer (6) 30 µm in thickness and an
30 Al layer (5) 30 µm in thickness;
- two-layer covers comprising a metallized PET layer (5) 30 µm in thickness and a binder layer (6) 30 µm in thickness;

- three-layer covers comprising a metallized PET layer (5) 30 μm in thickness a binder layer (6) 30 μm in thickness and a PP layer (7) 30 μm in thickness; and on packages comprising a PP container and such covers, the binder (6) being that as described in the previous example. These tests gave substantially the same values as those given in TABLE 1.

The binder used in the invention adheres well to metals (aluminium, steel, tinplate and metallized substrates), this adhesion being sufficient immediately after the extrusion coating to guarantee good dimensional stability of the structures during manufacture.

The binder is extremely suitable for high-speed coextrusion coating. It may be stretched during extrusion coating at rates greater than 100 m/min. without giving rise to undesirable width instability effects.

The binder also has good sealing/peel characteristics making it possible, in particular, during the sealing operation to guarantee that the packages are sealed perfectly and, during the peeling operation, to allow easy and progressive opening, and without any deposits.

Another advantage of the binder is its very good chemical inertness guaranteeing good organoleptic properties - no taste or smell - good resistance of the packaging in an aggressive environment (acidic food) and good steam sterilization behaviour.

Thus, another aspect of the invention resides in providing novel binders, especially those particularly suitable for producing the structure of the invention. Still other aspects of the invention are the processes used to produce the structure of the invention.

The preceding examples can be repeated with similar success by substituting the generically or specifically described reactants and/or operating conditions of this invention for those used in the preceding examples. Also, the preceding specific embodiments are to be construed as merely illustrative, and not limitative of the remainder of the disclosure in any way whatsoever.

The entire disclosure of all applications, patents and publications, cited above and below, and of corresponding French applications 00/04.037 and 00/08.790, are hereby incorporated by reference.

From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.
